Quick Start Guide

Gerald Q. Maguire Jr.

20 October 2026

Initial Steps

The initial steps are:

1. Copy the Overleaf project to your own project and include your name in this new project's name (use the "File →Make a copy").
2. Use "File →Settings →Compiler" to change the settings of "Main document" to `examplethesis.tex` and choose your compiler (you **must** select LuaLaTeX).
3. Fill out the `custom_configuration.tex` file - with information about yourself, your supervisors, and your working title.
4. The `examplethesis.tex` file is your main thesis file. Replace the example content with your own writing. I suggest you start by entering your draft abstract and configuring the `documentclass` with your language choice and whether you want to include papers, … .
5. Next, click the "Recompile" button. Now you have the example thesis with covers, title page, abstracts, and other preface pages, along with the body, example appendices, and examples of included papers (if you chose the `includepublications` option).

Timeouts

If you have just started a new session (or started working after a long idle time), you may experience a timeout. This commonly happens because the fonts that you are (or were) using are no longer in the font cache. If you think this is the case, then add an "early" `\end{document}` early in your document and compile again. Once the fonts are cached, you can comment out this early `\end{document}`. For a better solution, see the document `Saving_and_restoring_font_cache.tex`.

Using Overleaf and GitHub Integration

If you are used to working with GitHub, you might want to use the Overleaf and GitHub Integration. If you wish to use this integration or simply refer to work with a GitHub repository, see the repository `https://github.com/gqmaguirejr/KTH-3rd-cycle-template-restructured`. Note that this means that, as step 1, you should clone the repository and then make a new Overleaf project by importing from your GitHub repository.

Using the GitHub repository (or running scripts locally) enables automated functions that help you configure the `custom_configuration.tex` file, generate a list of included publications, and even create the tab pages, including the PDF of publications (if you have downloaded the publications).

When writing a compilation thesis, use the scripts

Use the scripts to make your job easier. The steps shown below will automatically generate files containing your list of publications, your contributions, the tabs for the included papers, and even help you check for the existence of your references. See the scripts and documentation at `https://github.com/gqmaguirejr/KTH-3rd-cycle-template-restructured`.

Listing 1: Configure your project, get publications from DiVA, add CReDiT information

```
# Configure your custom_configuration.tex file
streamlit run ./scripts/config_wizard.py
# Add your configuration data to your project; either manually or if using GitHub's automtion
# Get information about your publications from DiVA (uses your KTHID from custom_configuration.tex)
./scripts/DiVA_discovery.py
# Edit publications_map.json to indicate which publications you want to include, what labels you want, and their order
# Enter CReDiT info for your included papers
streamlit run ./scripts/CReDiT_Matrix_Wizard.py
# Automatically generate text for your thesis
./scripts/generate_publication_dividers.py
./scripts/generate_thesis_contributions.py
# Put the generated files into your thesis folder
# *** Write the rest of your Kappa ***
# Check the existence of the entries in your references.bib file
./scripts/bib_cleanup.py
# Compile your thesis
```

Tips for Writing and Navigating the Template

A quick way to start writing is to go to the table of contents in Overleaf and click a chapter or section; this will use a hyperlink to take you to that part of the PDF. Next, click on the left-pointing arrow near the top of the border between the LaTeX on the left and the PDF on the right; this will take you (close) to the correct place in the source file where you can start to modify the content and write.

Feel free to use `\begin{comment}` and `\end{comment}` to comment out regions of the body that you are not interested in. The comment package is one of the first packages in the `kththesis.cls` file, so you can use these two commands almost everywhere.

As you write, you will notice "todo" notes in the template. They follow the following conventions:

```
\generalExpl{Comments/directions/... in English}
\sweExpl{Text på svenska}
\engExpl{English descriptions about formatting}
\warningExpl{warnings}
```

If you do not want to see any of these notes, you can, of course, redefine the above macros to output nothing (they are defined in `lib/defines.tex`). To suppress all notes across the thesis, pass the `final` option to `\documentclass`.

Further documentation

As an author, you might want to start with the document `README_3rd_cycle_author.tex`. It provides more details on how to proceed and will hopefully answer most of your questions.

A parting tip: When in doubt about how to format a complex table, equation, algorithm, or subfigure, do not start from scratch. Inspect and copy the working examples in `examplethesis.tex` and the many accompanying `README` files; copying proven markup is the surest way to avoid syntax errors and unexpected layout surprises, while saving you time — which you can spend on *your* content.
